An Incidental Subepithelial Mass in the Esophagus

Gwang Ha Kim, M.D.
Department of Internal Medicine, Pusan National University School of Medicine, Busan, Korea

Age and Gender: 79/Male

Chief Complains: For evaluation of a subepithelial mass in the esophagus

Present Illness:
A 79-year-old man visited our hospital because of a subepithelial mass in the esophagus.

Past History: He underwent coronary artery bypass graft 13 years before due to myocardial infarction.

Family History: No

Physical Examination and Laboratory Findings:
There were no remarkable abnormal findings in physical examination and laboratory findings.

Endoscopic and Radiologic Findings:
Endoscopy shows a subepithelial mass in the mid-esophagus. It is covered by normal esophageal mucosa.
EUS shows a well-demarcated hypoechoic mass with nodular margin in the deep mucosal and submucosal layers.
PET-CT shows a hypermetabolic lesion in the mid-esophagus.

Hospital Progress:
Endoscopic submucosal dissection was performed.
